Security risk assessment report

Part 1: Select up to three hardening tools and methods to implement
1. Implementing stricter password policies. 2. Utilization of Multifactor Authentication (MFA). 3. Ensure updates for firewall configurations.

Part 2: Explain your recommendations
The three network hardening tools I recommend will dramatically improve the overall security and eliminate the data breach from happening again. Implementation of stricter password policy rules composed of using special characters, minimum characters required will make it harder for threat actors to guess using brute force. The same goes for MFA as it will double check and authenticate passwords with additional layers of authentication such as fingerprint or Eye-Match feature. Ensuring that firewall is up to date will also help to detect and eliminate possible threat from breaching the system/webhost.
